Reference: Air Quality Analysis for the Black Mountain Road Community Plan Amendment Project
(RECON Number 6524)

Dear Mr. Dumka:

The purpose of this report is to assess potential short-term local and regional air quality impacts resulting from the Black Mountain Road Community Plan Amendment (CPA) Project (project) located in the city of San Diego, California. The analysis of impacts is based on national and state Ambient Air Quality Standards (AAQS) and assessed in accordance with the regional guidelines, policies, and standards and the San Diego Air Pollution Control District (SDAPCD). As discussed in this analysis, all air quality impacts would be less than significant.

1.0 PROJECT DESCRIPTION

The project proposes to reclassify a segment of Black Mountain Road from a 6-lane Primary Arterial to a 4-lane Major. The project segment of Black Mountain Road subject to the CPA (project roadway) stretches approximately 1.3 miles from Twin Trails Drive on the north to the southern boundary of the Rancho Peñasquitos community adjacent to the Los Peñasquitos Canyon Preserve. The project roadway currently operates as a 4-lane Major with landscaped center medians, contiguous sidewalks, and Class II bike lanes. The bridge section of Black Mountain Road over State Route 56 (SR-56) is wider and operates as a 5-lane Primary Arterial. The project proposes a General Plan Amendment (GPA) to Figure LU-2, Land Use and Street System Map in the Land Use and Community Planning Element of the General Plan to reclassify the project roadway from a Prime Arterial to a Major Arterial, and a CPA to the Rancho Peñasquitos Community Plan Circulation Element to reclassify the project roadway from a 6-lane Primary Arterial to a 4-lane Major¹. The City of San Diego (City) Planning Commission initiated the CPA on February 27, 2014.

The project proposes the following roadway improvement as a design feature to increase the northbound to westbound left-turn pocket storage and improve the flow of northbound traffic (project design feature):

Restripe the segment of Black Mountain Road between the SR-56 westbound ramps and SR-56 eastbound ramps to include an additional northbound lane along Black Mountain Road from the SR-56 eastbound ramps to the middle of the overpass. To accommodate the additional northbound lane created by this restriping on the overpass, the roadway north of the overpass bridge would need to be widened for northbound traffic. The widening would extend approximately 0.15 mile from the SR-56 westbound off-ramp to the first commercial driveway to the north of the overpass.

¹ The City General Plan and Rancho Peñasquitos Community Plan use different nomenclature for roadway classifications. Consequently, the GPA would reclassify the project roadway as a Major Arterial, and the CPA would reclassify the project roadway as a 4-lane Major.

The following three roadway improvements identified in the Transportation Impact Study (TIS) would mitigate traffic impacts associated with the reclassification of the project roadway from a 6-lane Primary Arterial to a 4-lane Major:

- MM-TRA-1: Install a traffic signal at the intersection of Sundance Avenue and Twin Trails Drive.
- MM-TRA-2: Construct a continuous auxiliary lane on eastbound SR-56 between Camino Del Sur and Black Mountain Road.
- MM-TRA-3: Construct an additional on-ramp lane at the Rancho Peñasquitos Boulevard/SR-56 westbound on-ramp.

Figure 1 shows the regional location, while Figure 2 shows the locations of the project design feature and three traffic mitigation measures in relation to the project roadway. Figures 3 through 5 show the footprints of MM-TRA-2, MM-TRA-3, and the project design feature, respectively. A figure showing the footprint of MM-TRA-1 is not included since this traffic mitigation measure is limited to installation of a traffic signal.

Concurrent with the GPA and CPA, the project would also amend the Black Mountain Ranch Subarea Plan and Transportation Phasing Plan to remove the requirement to widen the project roadway to a 6-lane Primary Arterial and to add the project design feature and three traffic mitigation measures. As a part of this amendment, the Transportation Phasing Plan for Black Mountain Ranch would be updated to reflect the project and mitigation measures.

Implementation of the project would subsequently require amending the Rancho Peñasquitos, Black Mountain Ranch, and Pacific Highlands Ranch Public Facilities Financing Plans to remove the requirement to widen the project roadway to a 6-lane Primary Arterial and to add the project design feature and three traffic mitigation measures. At such time the Public Facilities Financing Plans are updated for the Rancho Peñasquitos, Black Mountain Ranch, and Pacific Highlands Ranch communities, any changes to reflect the project and mitigation measures adopted by this action would be incorporated.

2.0 ENVIRONMENTAL SETTING

The project site lies within the San Diego Air Basin (SDAB), which is regulated locally by the SDAPCD. Air quality at a given location is a function of the types and quantities of pollutants being emitted into the air locally and throughout the basin, and the dispersal rates of pollutants within the region. The major factors affecting pollutant dispersion are wind speed and direction, the vertical dispersion of pollutants (which is affected by inversions), and the local topography.

2.1 Regulatory Framework

2.2.1 Ambient Air Quality Standards

AAQS represent the maximum levels of background pollution considered safe, with an adequate margin of safety, to protect the public health and welfare. Six criteria pollutants of primary concern have been designated: ozone (O_3), carbon monoxide (CO), sulfur dioxide (SO_2), nitrogen dioxide (NO_2), lead (Pb), and respirable particulate matter (particulate matter less than 10 microns [PM_{10}] and particulate matter less than 2.5 microns [$PM_{2.5}$]). The U.S. Environmental Protection Agency (U.S. EPA) developed primary and secondary National AAQS (NAAQS). Additionally, the state of California has developed the California AAQS (CAAQS), which generally set limits that are more stringent on the criteria pollutants. The NAAQS and CAAQS are summarized in Table 1.

If an air basin is not in either federal or state attainment for a particular pollutant, the basin is classified as non-attainment area for that pollutant. The SDAB is currently classified as a federal non-attainment area for ozone. At the state level, the SDAB is classified a non-attainment area for ozone, PM_{10} , and $PM_{2.5}$.

	Rolling 3-Month Average	—		0.15 µg/m ³	Same as Primary Standard		
Visibility Reducing Particles ¹⁴	8 Hour	See footnote 14	Beta Attenuation and Transmittance through Filter Tape	No National Standards			
Sulfates	24 Hour	25 µg/m ³	Ion Chromatography				
Hydrogen Sulfide	1 Hour	0.03 ppm (42 µg/m ³)	Ultraviolet Fluorescence				
Vinyl Chloride ¹²	24 Hour	0.01 ppm (26 µg/m ³)	Gas Chromatography				

Table 1
Ambient Air Quality Standards

ppm = parts per million; ppb = parts per billion; $\mu\text{g}/\text{m}^3$ = micrograms per cubic meter; – = not applicable.

- ¹ California standards for ozone, CO (except 8-hour Lake Tahoe), SO₂ (1 and 24-hour), NO₂, particulate matter (PM₁₀, PM_{2.5}, and visibility reducing particles), are values that are not to be exceeded. All others are not to be equaled or exceeded. California AAQS are listed in the Table of Standards in Section 70200 of Title 17 of the California Code of Regulations.
- ² National standards (other than ozone, particulate matter, and those based on annual arithmetic mean) are not to be exceeded more than once a year. The ozone standard is attained when the fourth highest 8-hour concentration measured at each site in a year, averaged over three years, is equal to or less than the standard. For PM₁₀, the 24-hour standard is attained when the expected number of days per calendar year with a 24-hour average concentration above 150 $\mu\text{g}/\text{m}^3$ is equal to or less than one. For PM_{2.5}, the 24-hour standard is attained when 98 percent of the daily concentrations, averaged over three years, are equal to or less than the standard. Contact the U.S. EPA for further clarification and current national policies.
- ³ Concentration expressed first in units in which it was promulgated. Equivalent units given in parentheses are based upon a reference temperature of 25 degrees Celsius and a reference pressure of 760 torr. Most measurements of air quality are to be corrected to a reference temperature of 25 degrees Celsius and a reference pressure of 760 torr; ppm in this table refers to ppm by volume, or micromoles of pollutant per mole of gas.
- ⁴ Any equivalent measurement method which can be shown to the satisfaction of the California Air Resources Board (CARB) to give equivalent results at or near the level of the air quality standard may be used.
- ⁵ National Primary Standards: The levels of air quality necessary, with an adequate margin of safety to protect the public health.
- ⁶ National Secondary Standards: The levels of air quality necessary to protect the public welfare from any known or anticipated adverse effects of a pollutant.
- ⁷ Reference method as described by the U.S. EPA. An “equivalent method” of measurement may be used but must have a “consistent relationship to the reference method” and must be approved by the U.S. EPA.
- ⁸ On October 1, 2015, the national 8-hour ozone primary and secondary standards were lowered from 0.075 to 0.070 ppm.
- ⁹ On December 14, 2012, the national annual PM_{2.5} primary standard was lowered from 15 $\mu\text{g}/\text{m}^3$ to 12.0 $\mu\text{g}/\text{m}^3$. The existing national 24-hour PM_{2.5} standards (primary and secondary) were retained at 35 $\mu\text{g}/\text{m}^3$, as was the annual secondary standards of 15 $\mu\text{g}/\text{m}^3$. The existing 24-hour PM₁₀ standards (primary and secondary) of 150 $\mu\text{g}/\text{m}^3$ also were retained. The form of the annual primary and secondary standards is the annual mean, averaged over 3 years.
- ¹⁰ To attain the 1-hour national standard, the 3-year average of the annual 98th percentile of the 1-hour daily maximum concentrations at each site must not exceed 100 ppb. Note that the national standards are in units of ppb. California standards are in units of ppm. To directly compare the national standards to the California standards the units can be converted from ppb to ppm. In this case, the national standard of 100 ppb is identical to 0.100 ppm.
- ¹¹ On June 2, 2010, a new 1-hour SO₂ standard was established and the existing 24-hour and annual primary standards were revoked. To attain the 1-hour national standard, the 3-year average of the annual 99th percentile of the 1-hour daily maximum concentrations at each site must not exceed 75 ppb. The 1971 SO₂ national standards (24-hour and annual) remain in effect until one year after an area is designated for the 2010 standard, except that in areas designated nonattainment for the 1971 standards, the 1971 standards remain in effect until implementation plans to attain or maintain the 2010 standards are approved.
- Note that the 1-hour national standard is in units ppb. California standards are in units of ppm. To directly compare the 1-hour national standard to the California standard the units can be converted to ppm. In this case, the national standard of 75 ppb is identical to 0.075 ppm.
- ¹² CARB has identified lead and vinyl chloride as ‘toxic air contaminants’ with no threshold level of exposure for adverse health effects determined. These actions allow for the implementation of control measures at levels below the ambient concentrations specified for these pollutants.
- ¹³ The national standard for lead was revised on October 15, 2008 to a rolling 3-month average. The 1978 lead standard (1.5 $\mu\text{g}/\text{m}^3$ as a quarterly average) remains in effect until one year after an area is designated for the 2008 standard, except that in areas designated nonattainment for the 1978 standard, the 1978 standard remains in effect until implementation plans to attain or maintain the 2008 standard are approved.
- ¹⁴ In 1989, CARB converted both the general statewide 10-mile visibility standard and the Lake Tahoe 30-mile visibility standard to instrumental equivalents, which are “extinction of 0.23 per kilometer” and “extinction of 0.07 per kilometer” for the statewide and Lake Tahoe Air Basin standards, respectively.

2.2.2 State Implementation Plan

The State Implementation Plan (SIP) is a collection of documents that set forth the state's strategies for achieving AAQS. The SDAPCD is responsible for preparing and implementing the portion of the SIP applicable to the SDAB. The SDAPCD adopts rules, regulations, and programs to attain state and federal air quality standards, and appropriates money (including permit fees) to achieve its objectives.

2.2.3 Regional Air Quality Strategy

The SDAPCD prepared the original 1991/1992 Regional Air Quality Strategy (RAQS) in response to requirements set forth in the California Clean Air Act (CAA). The California CAA requires areas that are designated state non-attainment areas for ozone, CO, SO₂, and NO₂ prepare and implement plans to attain the standards by the earliest practicable date. The California CAA does not provide guidance on timing or requirements for attaining the state PM₁₀ and PM_{2.5} standards. Attached as part of the RAQS are the Transportation Control Measures (TCMs) adopted by the San Diego Association of Governments (SANDAG). Updates of the RAQS and corresponding TCM are required every three years. The RAQS and TCM set forth the steps needed to accomplish attainment of state and federal AAQS. The most recent update of the RAQS and TCM occurred in 2016.

2.2 Existing Air Quality

Air quality is commonly expressed as the number of days per year in which air pollution levels exceed federal standards set by the U.S. EPA or state standards set by the CARB. The SDAPCD maintains 10 air-quality monitoring stations located throughout the greater San Diego metropolitan region. Air pollutant concentrations and meteorological information are continuously recorded at these stations. Measurements are then used by scientists to help forecast daily air pollution levels.

The San Diego-Rancho Carmel Drive monitoring station, located at 11403 Rancho Carmel Drive approximately 3.5 miles northeast of the project site, is the closest monitoring station to the project site. The San Diego-Rancho Carmel Road monitoring station began operation in 2015 and measures CO, NO₂, and PM_{2.5}, however, only 2015 and 2016 NO₂ data is available. The nearest monitoring station that measures a wider range of data and pollutants is the San Diego-Kearny Villa Road monitoring station, located at 6125A Kearny Villa Road, approximately 7.5 miles southeast of the project site. The San Diego-Kearny Villa Road monitoring station measures ozone, NO₂, PM₁₀, and PM_{2.5}. Table 2 provides a summary of measurements collected at the San Diego-Rancho Carmel Road and San Diego-Kearny Villa Road monitoring stations for the years 2012 through 2016.

SOURCE: CARB 2017.					
ppm = parts per million; µg/m ³ = micrograms per cubic meter; -- = Not available.					
* Calculated days value. Calculated days are the estimated number of days that a measurement would have been greater than the level of the standard had measurements been collected every day. The number of days above the standard is not necessarily the number of violations of the standard for the year.					

3.0 THRESHOLDS OF SIGNIFICANCE

Thresholds used to evaluate potential impacts to air quality are based on applicable criteria in the California Environmental Quality Act Guidelines Appendix G and the City Significance Determination Thresholds. The project would have a significant air quality impact if it would (City of San Diego 2016):

1. Conflict with or obstruct implementation of the applicable air quality plan.
2. Result in a violation of any air quality standard or contribute substantially to an existing or projected air quality violation.
3. Expose sensitive receptors to substantial pollutant concentrations.
4. Create objectionable odors affecting a substantial number of people.
5. Result in exceeding 100 pounds per day of Particulate Matter (dust).
6. Result in substantial alteration of air movement in the area of the project.

The SDAPCD does not provide specific numeric thresholds for determining the significance of air quality impacts under the California Environmental Quality Act. However, the SDAPCD does specify Air Quality Impact Analysis trigger levels for new or modified stationary sources (SDAPCD Rules 20.1, 20.2, and 20.3). The SDAPCD does not consider these trigger levels to represent adverse air quality impacts, rather, if these trigger levels are exceeded by a project, the SDAPCD requires an air quality analysis to determine if a significant air quality impact would occur. While, these trigger levels do not generally apply to mobile sources or general land development projects, for comparative purposes these levels are used to evaluate the increased emissions that would be discharged to the SDAB if the project were approved.

The SDAPCD trigger levels are also utilized by the City Significance Determination Thresholds (City of San Diego 2016) as one of the considerations when determining the potential significance of air quality impacts for projects within the city. The air quality impact screening criteria used in this analysis are shown in Table 3.

Table 3 Air Quality Impact Screening Criteria			
Pollutant	Emission Rate		
	Pounds/Hour	Pounds/Day	Tons/Year
Nitrogen Oxides (NOx)	25	250	40
Sulfur Oxides (SOx)	25	250	40
CO	100	550	100
PM ₁₀	--	100	15
Lead	--	3.2	0.6
Volatile Organic Compounds, Reactive Organic Gases	--	137	15
PM _{2.5} *	--	67*	10

SOURCE: City of San Diego 2016.
* SDAPCD Resolution 16-041 was adopted on April 27, 2016. It amended Rules 20.1, 20.2, and 20.3. City of San Diego significance thresholds have not been updated to reflect this amendment.

4.0 EMISSION CALCUALTIONS

As the project would reclassify the project roadway from a 6-lane Primary Arterial to a 4-lane Major and implement roadway improvements, it would not generate additional traffic or increase vehicle miles traveled. The main source of project emissions would be associated with construction of the roadway improvements.

4.1 Construction Emissions

Construction-related activities are temporary, short-term sources of air emissions. Sources of construction-related air emissions include fugitive dust from grading activities; construction equipment exhaust; construction-related trips by workers, delivery trucks, and material-hauling trucks; and construction-related power consumption.

Construction-related pollutants result from dust raised during grading, emissions from construction vehicles, and chemicals used during construction. Fugitive dust emissions vary greatly during construction and are dependent on the amount and type of activity, silt content of the soil, and the weather. Vehicles moving over paved and unpaved surfaces, demolition, excavation, earth movement, grading, and wind erosion from exposed surfaces are all sources of fugitive dust. Construction operations are subject to the requirements established in SDAPCD Regulation 4, Rules 52, 54, and 55.

Heavy-duty construction equipment is usually diesel powered. In general, emissions from diesel-powered equipment contain more NOx, SOx, and particulate matter than gasoline-powered engines. However, diesel-powered engines generally produce less CO and less ROG than gasoline-powered engines. Standard construction equipment includes tractors, loaders, backhoes, rubber-tired dozers, excavators, graders, cranes, forklifts, rollers, paving equipment, generator sets, welders, cement and mortar mixers, and air compressors.

Air emissions were calculated using the Road Construction Emissions Model, Version 8.1.0 (Sacramento Metropolitan Air Quality Management District 2016). The model is a spreadsheet that estimates emissions based on numerous parameters regarding the type of construction, area to be disturbed, the period of construction and year of construction. Inputs were the length of the improvement, the type of improvement (new roadway or road widening), the year of construction, and area of construction. The roadway

construction emissions model estimates emissions from vehicle and equipment exhausts, fugitive dust, and off-gassing emissions during all phases of construction.

As discussed in Section 1.0, there are four proposed roadway improvements. Emissions due to construction of these improvements were calculated. The exact construction schedule and equipment required for these improvements is not known at this time. Emission calculations are based on model defaults and estimates of the maximum disturbance area based on preliminary concept drawings provided in the TIS prepared for the project (KOA Corporation 2016). It was assumed that installation of the signal at the intersection of Sundance Avenue and Twin Trails Drive would take five days and would require a crane and a drill rig. The auxiliary lane would be approximately 0.5 mile in length, and it was assumed that construction would last for six months. The ramp lane would be approximately 0.3 mile in length, and it was assumed that construction would last for one month. The segment of Black Mountain Road that would be widened would be approximately 0.15 mile in length, and it was assumed that construction would last for one month. The typical equipment required for roadway construction includes backhoes, crawler tractors, excavators, graders, loaders, rollers, scrapers, and signal boards. Additionally, construction of the auxiliary lane would require the reconstruction of an existing bridge. Therefore, in addition to the listed equipment, cranes and drill rigs were included in the emissions estimate.

Tables 4, 5, 6, and 7 summarize the construction emissions associated with installation of the traffic signal (MM-TRA-1), construction of the SR-56 auxiliary lane (MM-TRA-2), and construction of the Rancho Peñasquitos Boulevard/SR-56 on-ramp lane (MM-TRA-3), and Black Mountain Road restriping/widening (project design feature), respectively. Road Construction Emissions Model input and output are contained in Attachments 1 through 4.

Maximum Daily Emissions	4	45	30	0	14	4
<i>Significance Threshold</i>	137	250	550	250	100	67

For assessing the significance of the air quality emissions resulting during construction of the project, the construction emissions were compared to the significance thresholds shown in Tables 4 through 7. As shown, under all alternatives the maximum daily construction emissions associated with the project are projected to be less than the applicable thresholds for all criteria pollutants.

4.2 Operational Emissions

As discussed, the project would not generate additional trips. Implementation of the project would result in a future redistribution of vehicles on the roadway network in the vicinity of the project. However, based on the TIS prepared for the project which analyzed year 2050 traffic volumes on area roadways with and without implementation of the project, the project would not result in an increase in vehicle miles traveled on roadways in the vicinity of the project (KOA Corporation 2016). Therefore, the project would not result in an increase in mobile source emissions.

Area sources include consumer products, natural gas used in space and water heating, architectural coatings, landscaping equipment, hearths (fireplaces), and woodstoves. The project would not include any area sources of emissions.

5.0 IMPACT ANALYSIS

1. Would the project obstruct or conflict with the implementation of the San Diego RAQS?

The RAQS is the applicable regional air quality plan that sets forth the SDAPCD's strategies for achieving the NAAQS and CAAQS. The SDAB is designated a non-attainment area for the federal and state ozone standard. Accordingly, the RAQS was developed to identify feasible emission control measures and provide expeditious progress toward attaining the standards for ozone. The two pollutants addressed in the RAQS are ROG and NO_x, which are precursors to the formation of ozone. Projected increases in motor vehicle usage, population, and growth create challenges in controlling emissions and, by extension, to maintaining and improving air quality. The RAQS was most recently adopted in 2016.

The growth projections used by the SDAPCD to develop the RAQS emissions budgets are based on the population, vehicle trends, and land use plans developed in general plans and used by SANDAG in the development of the regional transportation plans and sustainable communities strategy. As such, projects that propose development that is consistent with the growth anticipated by SANDAG's growth projections and/or the General Plan would not conflict with the RAQS. In the event that a project would propose development that is less dense than anticipated by the growth projections, the project would likewise be consistent with the RAQS. In the event a project proposes development that is greater than anticipated in the growth projections, further analysis would be warranted to determine if the project would exceed the growth projections used in the RAQS for the specific subregional area.

The project would reclassify the project roadway from a 6-lane Primary Arterial to a 4-lane Major and implement roadway improvements. The project would not include any land use change or development that would result in growth. Therefore, the project would not obstruct or conflict with implementation of the SDAPCD RAQS, and impacts would be less than significant.

2. Would the project result in emissions that would violate any air quality standard or contribute substantially to an existing or projected air quality violation?

As shown in Tables 4 through 7, project construction would not exceed the applicable regional emissions thresholds. Further, should construction of all improvements occur simultaneously, total emissions would be less than the applicable thresholds. These thresholds are designed to provide limits below which project emissions would not significantly change regional air quality. Therefore, as project construction emissions would be well below these limits, project construction would not result in regional emissions that would exceed the NAAQS or CAAQS or contribute to existing violations. The project would not be a source of long-term emissions of regional air pollutants from operational sources, and impacts would be less than significant.

3. Would the project expose sensitive receptors to substantial pollutant concentrations?

Sensitive land uses include schools and schoolyards, parks and playgrounds, daycare centers, nursing homes, hospitals, and residential communities. There are residential uses located near the traffic improvement areas.

Construction of the project and associated infrastructure would result in short-term diesel exhaust emissions from on-site heavy-duty equipment. Construction of the project would result in the generation of diesel-exhaust diesel particulate matter (DPM) emissions from the use of off-road diesel equipment required for site grading and excavation, paving, and other construction activities and on-road diesel equipment used to bring materials to and from the project site.

Generation of DPM from construction projects typically occurs in a single area for a short period. According to the Office of Environmental Health Hazard Assessment (OEHHA), health risk assessments, which determine the exposure of sensitive receptors to toxic emissions, should be based on a 30-year exposure period; however, such assessments should be limited to the period/duration of activities associated with the project (OEHHA 2015). Thus, if the duration of proposed construction activities near any specific sensitive receptor were 12 months, the exposure would be less than 3 percent of the total exposure period used for health risk calculation.

Therefore, because of the limited size of the project and the short duration of construction, DPM generated by project construction is not expected to create conditions where the probability is greater than 10 in 1 million of contracting cancer for the Maximally Exposed Individual or to generate ground-level concentrations of noncarcinogenic toxic air contaminants that exceed a Hazard Index greater than 1 for the Maximally Exposed Individual. Additionally, with ongoing implementation of U.S. EPA and CARB requirements for cleaner fuels; off-road diesel engine retrofits; and new, low-emission diesel engine types, the DPM emissions of individual equipment would be substantially reduced over the years as the project construction continues. Therefore, project construction would not expose sensitive receptors to substantial pollutant concentration.

Localized CO concentration is a direct function of motor vehicle activity at signalized intersections (e.g., idling time and traffic flow conditions), particularly during peak commute hours and meteorological conditions. Under specific meteorological conditions (e.g., stable conditions that result in poor dispersion), CO concentrations may reach unhealthy levels with respect to local sensitive land uses. CO hotspots due to traffic almost exclusively occur at signalized intersections that operate at a level of service (LOS) E or below. Projects may result in or contribute to a CO hotspot if they worsen traffic flow at signalized intersections operating at LOS E or F.

Due to increased requirements for cleaner vehicles, equipment, and fuels, CO levels in the state have dropped substantially. All air basins are attainment or maintenance areas for CO. Therefore, more recent screening procedures based on more current methodologies have been developed. The Sacramento Metropolitan Air Quality Management District developed a screening threshold in 2011, which states that any project involving an intersection experiencing 31,600 vehicles per hour or more will require detailed analysis.

As discussed, the project would not generate traffic. However, implementation of the project would result in a future redistribution of vehicles on the roadway network in the vicinity of the project. The TIS prepared for the project analyzed future year 2050 intersection volumes with and without implementation of the project. Based on this analysis, four intersections are projected to operate at LOS E in year 2050; however, implementation of the project would decrease the delay and improve operation at these intersections. Additionally, the turning volumes at these intersections would be well below 31,600 vehicles per hour. Consequently, the project would reduce CO concentration at these four intersections and reduce the potential for CO hotspots. All other signalized intersections are projected to operate at LOS D or better and would not contribute to CO hotspots. Therefore, impacts associated with CO hot spots would be less than significant.

4. Would the project create objectionable odors affecting a substantial number of people?

The project does not include heavy industrial or agricultural uses that are typically associated with odor complaints. During construction, diesel equipment may generate some nuisance odors. Sensitive receptors near the project site include residential uses; however, exposure to odors associated with project construction would be short term and temporary in nature. Impacts would be less than significant.

5. Would the project result in exceed 100 pounds per day of particulate matter/dust?

As shown in Tables 4 through 7, project construction would not result in more than 100 pounds per day of particulate matter. Impacts would be less than significant.

6. Would the project result in a substantial alteration of air movement in the area?

Local topographic variation such as that caused by the height and shape of a row of buildings can influence air movement in a given location (Boston Redevelopment Authority 1986). Alterations in the built environment may increase the dispersion of air pollutants or cause stagnation that may result in a harmful concentration of air pollutants. Urban canyons are places where the street is flanked by buildings on both sides creating a canyon-like environment. Where urban canyons are oriented perpendicular to the prevailing wind patterns, the likelihood of restricted air movement and associated pollutant accumulation may increase. The project would not construct any buildings or structures. Therefore, there would be no impact associated with the alteration of air movement.

6.0 CONCLUSIONS

The primary goal of the RAQS is to reduce ozone precursor emissions. Consistency with the RAQS is determined by analyzing a project with the assumptions in the RAQS. The project would reclassify the project roadway from a 6-lane Primary Arterial to a 4-lane Major and implement roadway improvements. The project would not include any land use change or development that would result in growth. Therefore, the project would not obstruct or conflict with implementation of the SDAPCD's RAQS, and impacts would be less than significant.

The project would not generate additional traffic or increase vehicle miles traveled. The main source of project emissions would be associated with construction of the roadway improvements. Construction emissions were calculated for the installation of the traffic signal (MM-TRA-1), the addition of the SR-56 auxiliary lane (MM-TRA-2), the additional Rancho Peñasquitos Boulevard/SR-56 on-ramp lane (MM-TRA-3),

Mr. William Dumka
Page 17
March 22, 2019

and the restriping/widening of a portion of Black Mountain Road (project design feature). As shown in Tables 4 through 7, project construction emissions would not exceed the applicable regional emissions thresholds. These thresholds are designed to provide limits below which project emissions would not significantly change regional air quality. Therefore, as project emissions are well below these limits, project construction and operation would not result in regional emissions that would exceed the NAAQS or CAAQS or contribute to existing violations. Additionally, construction emissions would be temporary, intermittent, and would cease at the end of project construction.

Further, the project would not result in the exposure of sensitive receptors to substantial pollutant concentrations, generate odors that would affect a substantial number of people, or alter air movement in the area. Air quality impacts would be less than significant.

If you have any questions about the results of this analysis, please contact me at jfleming@reconenvironmental.com or (619) 308-9333 x177.

Sincerely,

Jessica Fleming
Associate Environmental Analyst

PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified.

Total PM10 emissions shown in column F are the sum of exhaust and fugitive dust emissions shown in columns G and H. Total PM2.5 emissions shown in Column I are the sum of exhaust and fugitive dust emissions shown in columns J and K.

CO₂e emissions are estimated by multiplying mass emissions for each GHG by its global warming potential (GWP), 1, 25 and 298 for CO₂, CH₄ and N₂O, respectively. Total CO₂e is then estimated by summing CO₂e estimates over all GHGs.

PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified

Total PM10 emissions shown in column F are the sum of exhaust and fugitive dust emissions shown in columns G and H. Total PM2.5 emissions shown in Column I are the sum of exhaust and fugitive dust emissions shown in columns J and K.

Total F-M-10 emissions shown in Column 1 are the sum of exhaust and fugitive dust emissions shown in columns 3 and 11. Total F-M-2.5 emissions shown in Column 1 are the sum of exhaust and fugitive dust emissions shown in columns 3 and 9. CO₂ emissions are estimated by multiplying mass emissions for each GHG by its global warming potential (GWP) – 1, 25 and 298 for CO₂, CH₄ and N₂O, respectively. Total CO₂ is then estimated by summing CO₂ estimates over all GHGs.

The CO₂e emissions are reported as metric tons per phase.

Road Construction Emissions Model

Data Entry Worksheet

Version 8.1.0

Note: Required data input sections have a yellow background.

Optional data input sections have a blue background. Only areas with a yellow or blue background can be modified. Program defaults have a white background.

The user is required to enter information in cells D10 through D24, E28 through G35, and D38 through D41 for all project types.

Please use "Clear Data Input & User Overrides" button first before changing the Project Type or begin a new project.

Input Type

Project Name

Black Mountain Road Auxiliary Lane

Construction Start Year

2018

Enter a Year between 2014 and 2025
(inclusive)

Project Type

2

- 1) New Road Construction : Project to build a roadway from bare ground, which generally requires more site preparation than widening an existing roadway
- 2) Road Widening : Project to add a new lane to an existing roadway
- 3) Bridge/Overpass Construction : Project to build an elevated roadway, which generally requires some different equipment than a new roadway, such as a crane
- 4) Other Linear Project Type: Non-roadway project such as a pipeline, transmission line, or levee construction

Project Construction Time

6.00

months

Working Days per Month

22.00

days (assume 22 if unknown)

Predominant Soil/Site Type: Enter 1, 2, or 3
(for project within "Sacramento County", follow soil type selection
instructions in cells E18 to E20 otherwise see instructions provided in
cells J18 to J22)

2

- 1) Sand Gravel : Use for quaternary deposits (Delta/West County)
- 2) Weathered Rock-Earth : Use for Laguna formation (Jackson Highway area) or the lone formation (Scott Road, Rancho Murieta)
- 3) Blasted Rock : Use for Salt Springs State or Copper Hill Volcanics (Folsom South of Highway 50, Rancho Murieta)

Project Length

0.50

miles

Total Project Area

2.20

acres

Maximum Area Disturbed/Day

0.50

acres

Water Trucks Used?

2

1. Yes
2. No

To begin a new project, click this button to clear data previously entered. This button will only work if you opted not to disable macros when loading this spreadsheet.

Please note that the soil type instructions provided in cells E18 to E20 are specific to Sacramento County. Maps available from the California Geologic Survey (see weblink below) can be used to determine soil type outside Sacramento County.

http://www.conservancy.ca.gov/cgs/information/geologic_mapping/Pages/googlemaps.aspx#regionalseries

Material Hauling Quantity Input

Material Type	Phase	Haul Truck Capacity (yd ³) (assume 20 if unknown)	Import Volume (yd ³ /day)	Export Volume (yd ³ /day)
Soil	Grubbing/Land Clearing			
	Grading/Excavation			
	Drainage/Utilities/Sub-Grade			
Asphalt	Paving			
	Grubbing/Land Clearing			
	Grading/Excavation			
	Drainage/Utilities/Sub-Grade			
	Paving			

Mitigation Options

On-road Fleet Emissions Mitigation

Select "2010 and Newer On-road Vehicles Fleet" option when the on-road heavy-duty truck fleet for the project will be limited to vehicles of model year 2010 or newer
Select "20% NOx and 45% Exhaust PM reduction" option if the project will be required to use a lower emitting off-road construction fleet. The SMAQMD Construction Mitigation Calculator can be used to confirm compliance with this mitigation measure (<http://www.airquality.org/ceqa/mitigation.shtml>).
Select "Tier 4 Equipment" option if some or all off-road equipment used for the project meets CARB Tier 4 Standard

The remaining sections of this sheet contain areas that can be modified by the user, although those modifications are optional.

Note: The program's estimates of construction period phase length can be overridden in cells D50 through D53, and F50 through F53.

Construction Periods	User Override of Construction Months	Program Calculated Months	User Override of Phase Starting Date	Program Default Phase Starting Date
Grubbing/Land Clearing		0.60		1/1/2018
Grading/Excavation		2.70		1/20/2018
Drainage/Utilities/Sub-Grade		1.80		4/13/2018
Paving		0.90		6/7/2018
Totals (Months)		6		

Note: Soil Hauling emission default values can be overridden in cells D61 through D64, and F61 through F64.

Note: Asphalt Hauling emission default values can be overridden in cells D87 through D90, and F87 through F90.

Note: Worker commute default values can be overridden in cells D113 through D118.

ng	0	0	0	0	400	0

PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified.

Total PM10 emissions shown in column F are the sum of exhaust and fugitive dust emissions shown in columns G and H. Total PM2.5 emissions shown in Column I are the sum of exhaust and fugitive dust emissions shown in columns J and K.

CO₂e emissions are estimated by multiplying mass emissions for each GHG by its global warming potential (GWP), 1, 25 and 298 for CO₂, CH₄ and N₂O, respectively. Total CO₂e is then estimated by summing CO₂e estimates over all GHGs.

PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified.

Total PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified.

Total PM10 emissions shown in column F are the sum of exhaust and fugitive dust emissions shown in columns G and H. Total PM2.5 emissions shown in Column I are the sum of exhaust and fugitive dust emissions shown in columns J and K. CO₂ emissions are calculated by multiplying emissions from each GHG outlet by its potential (GWP) of 1.05. CO₂, CH₄, N₂O, and T_{CO₂} is the estimated value for CO₂ emissions and CH₄, N₂O, and T_{CO₂} is the estimated value for CH₄, N₂O, and T_{CO₂} respectively.

CO₂e emissions are estimated by multiplying mass emissions by GWP values.

on	0	0	0	0	800	0
e	0	0	0	0	560	0
ng	0	0	0	0	400	0

PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified.

Total PM10 emissions shown in column F are the sum of exhaust and fugitive dust emissions shown in columns G and H. Total PM2.5 emissions shown in Column I are the sum of exhaust and fugitive dust emissions shown in columns J and K.

CO₂e emissions are estimated by multiplying mass emissions for each GHG by its global warming potential (GWP), 1, 25 and 298 for CO₂, CH₄ and N₂O, respectively. Total CO₂e is then estimated by summing CO₂e estimates over all GHGs.

PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified.

Total PM10 and PM2.5 estimates assume 50% control of fugitive dust from watering and associated dust control measures if a minimum number of water trucks are specified.

Total PM10 emissions shown in column F are the sum of exhaust and fugitive dust emissions shown in columns G and H. Total PM2.5 emissions shown in Column I are the sum of exhaust and fugitive dust emissions shown in columns J and K. CO₂ emissions are calculated by multiplying emissions from each GHG outlet by its potential (GWP) of 1.05. CO₂, CH₄, N₂O, and T_{CO₂} is the estimated value for CO₂ emissions and CH₄, N₂O, and T_{CO₂} is the estimated value for CH₄, N₂O, and T_{CO₂} respectively.

CO₂e emissions are estimated by multiplying mass emissions by GWP values.
