This section of the Draft Environmental Impact Report (Draft EIR) evaluates the potential for the proposed Section 31 Specific Plan Project ("Section 31 Specific Plan" or "Project") to result in noise impacts within the Project Site and surrounding communities. This evaluation uses procedures and methodologies as specified by the California Department of Transportation (Caltrans), the Federal Transit Administration (FTA), and the Federal Highway Administration (FHWA). Noise monitoring and roadway noise modeling datasheets are included in **Appendix H: Noise Worksheets** of this Draft EIR.

Prior to the preparation of this Draft EIR, an Initial Study (included in **Appendix A** of this Draft EIR) was prepared using the CEQA Guidelines Appendix G Environmental Checklist Form to assess potential environmental impacts associated with noise. The following Initial Study screening criterion related to noise does not require additional analysis in this Draft EIR:

• Potential impacts related to the exposure of people residing or working in the Project area to excessive noise levels for a project located within the vicinity of a private airstrip or an airport land use plan or, where such a plan has not been adopted, within two miles of a public airport or public use airport were evaluated and determined to have "No Impact" in the Initial Study. The Project Site is not within two miles of a public airport. Therefore, this issue is not addressed any further within this section.

Impacts found to be less than significant are further discussed in **Section 8.1: Effects Not Found to be Significant** of this Draft EIR. Please see **Section 9.0** for a glossary of terms, definitions, and acronyms used in this Draft EIR.

A. ENVIRONMENTAL SETTING

1. Fundamentals of Noise

Sound is mechanical energy transmitted by pressure waves in a compressible medium such as air. Noise is generally defined as unwanted sound. Sound is characterized by various parameters that describe the physical properties of sound waves. These properties include the rate of oscillation (frequency); the distance between successive high and low noise levels, the speed of propagation; and the pressure level or energy content of a given sound wave. In particular, the sound pressure level has become the most common descriptor used to characterize the loudness of an ambient sound level.

The unit of sound pressure expressed as a ratio to the faintest sound detectable to a person with normal hearing is called a decibel (dB). Sound or noise can vary in intensity by more than one million times within the range of human hearing. A logarithmic loudness scale, similar to the Richter scale for earthquake magnitude, is used to describe sound-intensity levels. The human ear is not equally sensitive to all sound

frequencies within the entire spectrum. Noise levels at maximum human sensitivity are factored more heavily into sound descriptions in a process called A weighting, written as dBA. Further reference to decibels in this analysis should be understood to be A-weighted.

Several noise descriptors have been developed to evaluate the adverse effect of community noise on people. Since noise level fluctuates over time, an equivalent sound level (Leq) descriptor is used to describe typical time-varying instantaneous noise. Finally, because community receptors are more sensitive to unwanted noise intrusion during evening and nighttime hours, State law requires that an artificial decibel increment be added to noise occurring during those time periods. The 24-hour noise descriptor with a specified evening (7:00 to 10:00 PM) and nighttime (10:00 PM to 7:00 AM) penalty is called the Community Noise Equivalent Level (CNEL).

Noise sources can generally be categorized as one of two types: (1) point sources, such as stationary mechanical equipment; and (2) line sources, such as a roadway. Sound generated by a point source typically diminishes (attenuates) at a rate of 6 dBA for each doubling of distance from the source to the receptor at acoustically hard sites, and at a rate of 7.5 dBA at acoustically soft sites. A hard, or reflective site consists of asphalt, concrete, or very hard-packed soil, which does not provide any excess ground-effect attenuation. An acoustically soft or absorptive site is characteristic of normal earth and most ground with vegetation. As an example, a 60-dBA noise level measured at 50 feet from a point source at an acoustically hard site would be 54 dBA at 100 feet from the source and 48 dBA at 200 feet from the source. Noise from the same point source at an acoustically soft site would be 52.5 dBA at 100 feet and 45 dBA at 200 feet from the source. Sound generated by a line source typically attenuates at a rate of 3 dBA and 4.5 dBA per doubling of distance from the source to the receptor for hard and soft sites, respectively. Noise levels generated by a variety of activities are shown in Figure 5.11-1: Common Noise Levels. Man-made or natural barriers can also attenuate sound levels, as illustrated in Figure 5.11-2: Noise Attenuation by Barriers.

2. Noise Terminology

Different types of scales are used to characterize the time-varying nature of sound. Applicable scales include the maximum noise level (Lmax), equivalent noise level (Leq), and the CNEL. Lmax is the maximum noise level measured during a specified period. Leq is the average A-weighted sound level measured over a given time interval. Leq can be measured over any period, but is typically measured for 1-minute, 15-minute, 1-hour, or 24-hour periods. CNEL is an average A-weighted sound level measured

FIGURE **5.11-1**

"Barrier Effect" Resulting from Differences in Elevation.

"Barrier Effect" Resulting from Typical Soundwall.

over a 24-hour period. However, this noise scale is adjusted to account for some individuals' increased sensitivity to noise levels during the evening and nighttime hours. A CNEL noise measurement is obtained by adding 5 dB(A) to sound levels occurring during the evening, from 7:00 PM to 10:00 PM, and 10 dB(A) to sound levels occurring during the nighttime, from 10:00 PM to 7:00 AM. The 5 dB(A) and 10 dB(A) "penalties" are applied to account for increased noise sensitivity during the evening and nighttime hours. Day-night average level (Ldn) is the A-weighted equivalent sound level for a 24-hour period with an additional 10 dB imposed on the equivalent sound levels for nighttime hours of 10:00 PM to 7:00 AM. Table 5.11-1: Noise Descriptors, identifies various noise descriptors developed to measure sound levels over different periods of time.

3. Noise Barrier Attenuation

The introduction of a barrier between a noise source and a sensitive receptor redistributes the sound energy into several paths, including a diffracted path over the top of the barrier, a transmitted path through the barrier, and a reflected path directed away from the sensitive receptor. Diffraction is the bending of sound waves over the top of a barrier. The area behind the barrier in which diffraction occurs is known as a "shadow zone," and sensitive receptors located in this area will experience some sound attenuation. The amount of attenuation is related to the magnitude of the diffraction angle. The diffraction angle will increase if the barrier height increases or if the distance from sensitive receptors is decreased to the barrier. In addition to diffraction with the use of barriers, sound can travel through the barrier itself. The level of sound transmission through the barrier depends on factors relating to the composition of the barrier (such as its weight and stiffness), the angle of incidence of the sound, and the frequency spectrum of the sound. The rating of a material's ability to transmit noise is called transmission loss. Transmission loss is related to the ratio of the incident noise energy to the transmitted noise energy, and it is normally expressed in decibels, which represents the amount noise levels will be reduced when the sound waves pass through the material of the barrier.

Table 5.11-1 Noise Descriptors

| Term | Definition |
|---|---|
| Sound | A disturbance created by a vibrating object, which, when transmitted by pressure waves through a medium such as air, is capable of being detected by a receiving mechanism, such as the human ear or a microphone. |
| Noise | Sound that is loud, unpleasant, unexpected, or otherwise undesirable. |
| Decibel (dB) | The unit for measuring the volume of sound equal to 10 times the logarithm (base 10) of the ratio of the pressure of a measure sound to a reference pressure. |
| A-Weighted Decibel (dB[A]) | A sound measurement scale that adjusts the pressure of individual frequencies according to human sensitivities. The scale accounts for the fact that the region of highest sensitivity for the human ear is between 2,000 and 4,000 cycles per second (hertz). |
| Equivalent Continuous Sound Level (Leq) | The sound level containing the same total energy as a time varying signal over a given time period. The Leq is the value that expresses the time averaged total energy of a fluctuating sound level. Leq can be measured over any time period, but is typically measured for 1-minute, 15-minute, 1-hour, or 24-hour periods. |
| Day-Night Level (Ldn) | The energy average of the A-weighted sound levels occurring during a 24-hour period with 10 dB(A) added sound levels occurring from 10 PM to 7 AM. |
| Community Noise Equivalent Level (CNEL) | A rating of community noise exposure to all sources of sound that differentiates between daytime, evening, and nighttime noise exposure. These adjustments add 5 dB(A) for the evening, 7:00 PM to 10:00 PM, and add 10 dB(A) for the night, 10:00 PM to 7:00 AM. The 5 and 10 decibel penalties are applied to account for increased noise sensitivity during the evening and nighttime hours. The logarithmic effect of adding these penalties to the 1-hour Leq measurements typically results in a CNEL measurement that is within approximately 3 dB(A) of the peak-hour Leq.1 |
| sound pressure level | The sound pressure is the force of sound on a surface area perpendicular to the direction of the sound. The sound pressure level is expressed in dB. |
| Ambient Noise | The level of noise that is all encompassing within a given environment, being usually a composite of sounds from many and varied sources near to and far from the observer. No specific source is identified in the ambient environment. |

Note: California Department of Transportation, Technical Noise Supplement; A Technical Supplement to the Traffic Noise Analysis Protocol, (Sacramento, CA: November 2009), N51-N54.

Noise energy can also be reflected by a barrier wall. The reflected sound energy thus would not affect the sensitive receptor but may affect sensitive receptors to the left and right of the developed barrier.³ Manmade or natural barriers can also attenuate sound levels, as illustrated in **Figure 5.11-3: Noise Barrier Diffraction**. A solid wall or berm may reduce noise levels by 5 to 10 dB(A).⁴

Contemporary wood frame construction techniques in California typically provide about 25 dB(A) reduction in exterior to interior noise levels. This is due to structural means used to comply with California regulations, such as the Title 24 energy conservation standards. The minimum attenuation of exterior to interior noise provided by typical structures in California is provided in **Table 5.11-2: Attenuation of Typical Structures.**

Table 5.11-2
Noise Attenuation of Typical Structures

| Building Type | Open Windows (dB[A]) | Closed Windows (dB[A]) ^a |
|------------------------------|-------------------------|--|
| Residences | 17.0 | 25.0 |
| Churches | 20.0 | 30.0 |
| Hospitals/convalescent homes | 17.0 | 25.0 |
| Offices | 17.0 | 25.0 |
| Theaters | 20.0 | 30.0 |
| Hotels/motels | 17.0 | 25.0 |

4. Vibration

Vibration consists of waves transmitted through a solid medium. Groundborne vibration propagates from the source through the ground to adjacent buildings by surface waves. A vibration may be a single pulse, a series of pulses, or a continuous oscillatory motion. The frequency of a vibrating object describes how rapidly it is oscillating, measured in hertz (Hz). Most environmental vibrations consist of a composite, or "spectrum," of many frequencies, and are generally classified as broadband or random vibrations. **Figure 5.11-4: Typical Levels of Groundborne Vibration**, identifies typical groundborne vibration levels. The normal frequency range of most groundborne vibration that can be felt starts from a low frequency of less than 1 Hz to a high of about 200 Hz. Vibration is often measured in terms of the peak particle velocity (PPV) in inches per second (in/sec), because it is related to the stresses that are experienced by buildings. Vibration is also measured in vibration decibels (VdB). The human threshold of perception is approximately 65 VdB. A vibration velocity of 75 VdB is the approximate dividing line between barely perceptible and distinctly perceptible levels for many people. Vibration levels are acceptable at approximately 85 VdB if there are an infrequent number of events per day.⁵

Vibration energy attenuates as it travels through the ground, causing the vibration amplitude to decrease with distance away from the source.⁶ High frequency vibrations reduce much more rapidly than low frequencies, so that in the far-field from a source, the low frequencies tend to dominate. Soil properties also affect the propagation of vibration. When groundborne vibration interacts with a building, there is usually a ground-to-foundation coupling loss, but the vibration can also be amplified by the structural resonances of the walls and floors.⁷ Vibration in buildings is typically perceived as rattling of windows or of items on shelves, or the motion of building surfaces.

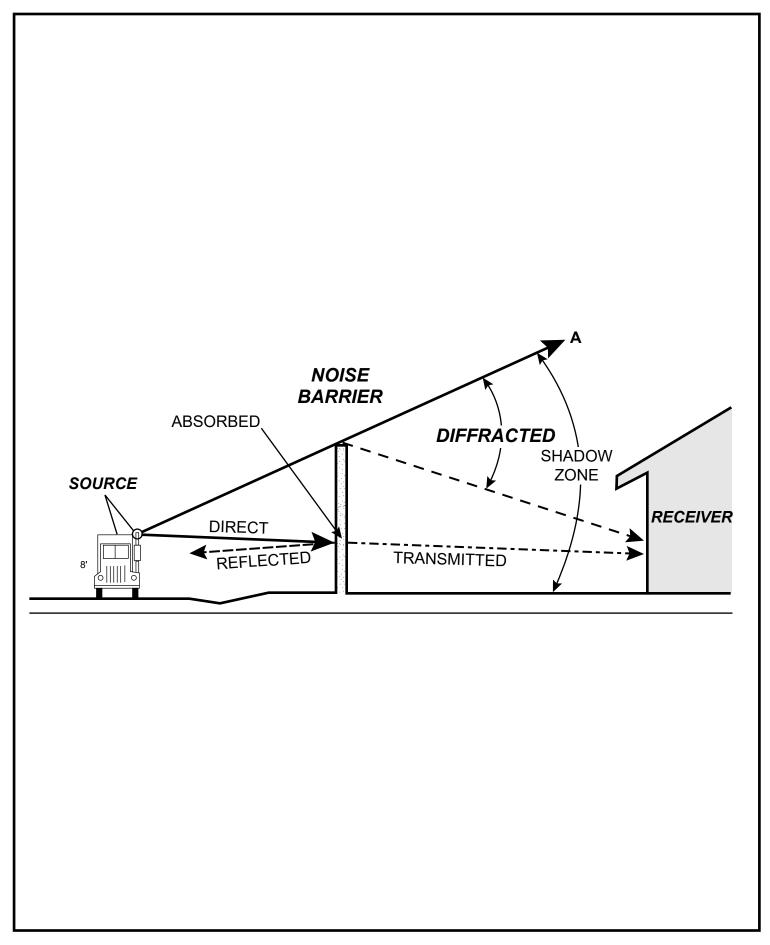

Groundborne vibration is generally limited to areas within a few hundred feet of certain types of construction activities, especially pile driving. Road vehicles rarely create enough groundborne vibration to be perceptible to humans unless the road surface is poorly maintained and there are potholes or bumps. If traffic, typically heavy trucks, induces perceptible vibration in buildings, such as window rattling or shaking of small loose items, then it is most likely an effect of low-frequency airborne noise or ground characteristics. Human annoyance by vibration is related to the vibration energy and the number and duration of events, as well as the setting in which the person experiences the vibration. As discussed previously, vibration can be amplified by the structural resonances of the walls and floors of buildings. The more the events or the greater the duration, the more annoying will it be to humans.

⁷ Federal Transit Administration Transit Noise and Vibration Impact Assessment Manual, September 2018, 7-1, 7-2.

⁸ Federal Transit Administration (2018), 7-9.

PPV is typically a factor 1.7 to 6 times greater than RMS vibration velocity. A factor of 4 was used to calculate noise levels.

FIGURE **5.11-4**

Vibration levels in terms of velocity levels are defined as: V=20 x log (a/r)
V=velocity levels in decibels
a=RMS velocity amplitude
r=reference amplitude (accepted reference quantities for vibration velocity are 1 x 10⁻⁶ inches/second in the United States)

5. Existing Conditions

The approximately 618-acre Project Site is located in and surrounded by the City of Rancho Mirage ("City") to the north, south, southeast, and west, and by the City of Palm Desert to the east. The City is considered to be in the heart of the Coachella Valley in Riverside County, nestled at the base of the Santa Rosa and San Jacinto Mountains and conveniently located to utilize the southern California freeway system via Interstate 10 (I-10). The majority of future development in this area of the Coachella Valley is expected to occur near the I-10 corridor.

Existing Noise Levels

The Project Site is currently vacant. While there are no existing stationary- or mobile-sources of noise within the Project Site, the site is surrounded by transportation and stationary sources of noise that contribute to the existing ambient noise environment. The Project Site is bound by Gerald Ford Drive on the north; Monterey Avenue on the east; Frank Sinatra Drive on the south; and Bob Hope Drive on the west. In addition to mobile and stationary sources of noise, the Coachella Valley also experiences high wind gusts that can significantly elevate the ambient noise environment on windy days.

Noise measurements, as discussed below, were conducted at 8 off-site locations adjacent to the Project site area to establish baseline noise conditions. The noise measurements locations are shown in **Figure 5.11-5**: **Noise Monitoring and Sensitive Receptor Location Map** and described in **Table 5.11-3**: **Existing Ambient Noise Levels**. Existing noise levels ranged from a low of 69.3 dBA Leq at Site 3 (residences north of the Project site area across Gerald Ford Drive) to a high of 73.7 dBA Leq Site 8 (residences to the east across Monterey Avenue). Based on the land use noise compatibility criteria, forecasted noise levels are classified as conditionally acceptable for Site 3, 6, and 7 and normally unacceptable for Site 1, 2, 4, 5 and 8.9 As discussed above, the predominant noise source in the Project site vicinity is motor vehicle travel, particularly along the adjacent major streets such as Gerald Ford Drive to the north, Frank Sinatra Drive to the south, Monterey Avenue to the east and Bob Hope Drive to the west.

| Site 8 | East of Project Site, near Monterey Avenue and Shadow Ridge Road | Lodging | 73.7 |

Existing Off-Site Roadway Noise Levels

In addition to the ambient noise measurements near the Project site, the existing traffic noise on local roadways in the surrounding areas was calculated to quantify the 24-hour CNEL noise levels using information provided in the traffic impact study.¹⁰

A total of 32 intersections, 5 access intersections, and 2 roadway segments, were selected for the analysis of existing off-site traffic noise and the potential increases in traffic volumes from the Project site. Given that motor vehicle travel is the predominant noise source within the Project vicinity, the analysis focuses on sensitive uses located along the major roadways within the vicinity. Traffic noise levels were calculated using the Federal Highway Administration Traffic Noise Model (FHWA TNM).

FIGURE **5.11-5**

Table 5.11-4: Existing Roadway Traffic Noise Levels, provides the calculated CNEL for the analyzed local roadway segments based on existing traffic volumes. CNEL levels attributed to roadway traffic only range from 42.1 dBA CNEL for residential receptors at the Sunnylands Centers to 71.6 dBA CNEL for residential receptors along Monterey Avenue. In terms of the City's land use noise compatibility categories based on roadway traffic only, most locations are classified as normally unacceptable, with others classified as normally acceptable. Specifically, the noise exposure compatibility categories based on roadway traffic only are summarized as follows:

- Normally and Conditionally acceptable: Locations along I-10 Ramps, Ramon Road, Varner Road, Dinah Shore Drive, Gerald Ford Drive, Shadow Ridge Road, Sunny Lands Center, Frank Sinatra Drive, Country Club Drive, Hovley Lane, Fred Waring Drive, Dale Palm Drive, SR 111, Da Vall Drive, Rattler Road, Morningside Drive, Bob Hope Drive, Oasis Way, Kavendish Way, Monterey Avenue (except for segment north and south of Hovley Lane which is classified as normally unacceptable), Varner Road, Portola Road/Avenue, and Cook Street.
- Normally unacceptable: Locations along Monterey Avenue north and south of Hovley Lane.
- Clearly unacceptable: None.

N/A: No Data.

Existing Vibration Conditions

The primary source of existing groundborne vibration in the vicinity of the Project Site is vehicle traffic on Gerald Ford Drive, Monterey Avenue, Frank Sinatra Drive, and Bob Hope Drive. According to the FTA, 11 typical road traffic-induced vibration levels are unlikely to be perceptible by people. In part, FTA indicates that "it is unusual for vibration from traffic including buses and trucks to be perceptible, even in a location close to major roadways." Therefore, based on FTA published vibration data, the existing ground vibration environment in the Project vicinity would be below the perceptible levels. Trucks and buses typically generate vibration velocity levels of approximately 63 VdB (at 50 feet distance), and these levels could reach 72 VdB when trucks and buses pass over bumps in the road.

¹¹ Federal Transit Administration, Transit Noise and Vibration Impact Assessment (2018).

6. Regulatory Setting

Federal

Department of Housing and Urban Development

The US Department of Housing and Urban Development (HUD) has set a goal of 65 dB(A) CNEL as a desirable maximum exterior standard for residential uses developed under HUD funding. While HUD does not specify acceptable interior noise levels, standard construction of residential uses constructed under Title 24 standards typically provides in excess of 20 dB(A) of attenuation with the windows closed. Based on this premise, the interior CNEL should not exceed 45 dB(A) CNEL.¹²

Federal Transit Administration

The FTA has published a technical manual, *Transit Noise and Vibration Impacts Assessment*, that provides ground-borne vibration impact criteria with respect to building damage during construction activities. ¹³ According to the FTA guidelines, a vibration criterion of 0.20 PPV should be considered as the significant impact level for nonengineered timber and masonry buildings. Structures or buildings constructed of reinforced concrete, steel, or timber have a vibration damage criterion of 0.50 PPV based on the FTA guidelines. Structures amplify ground-borne vibration, and wood-frame buildings, such as typical residential structures, are more affected by ground vibration than are heavier buildings. The level at which ground-borne vibration is strong enough to cause architectural damage has not been determined conclusively. The most conservative estimates are reflected in the FTA standards, shown in **Table 5.11-5: Construction Vibration Damage Criteria**. The FTA has also adopted standards for ground-borne vibration impacts related to human annoyance, as shown in **Table 5.11-6: Ground-borne Vibration Sensitivity Criteria**. These criteria are based on extensive research that suggests humans are sensitive to vibration velocities in the range of 8 to 80 Hz. ¹⁴

State

Noise Standards

The California Department of Health Services (DHS) has established guidelines for evaluating the compatibility of various land uses as a function of community noise exposure; these guidelines have been included in the State of California General Plan Guidelines, which is published and updated by the

¹ This criterion limit is based on levels that are acceptable for most moderately sensitive equipment such as optical microscopes. For equipment that is more sensitive, a Detailed Vibration Analysis must be performed.

Governor's Office of Planning and Research. ¹⁵ According to the State, an exterior noise environment up to 60 dBA CNEL and 65 dBA CNEL is "normally acceptable" for single- and multifamily residential uses, respectively, without special noise insulation requirements. In addition, noise levels up to 75 dBA CNEL are "conditionally acceptable" with special noise insulation requirements, while noise levels at 75 dBA CNEL and above are "clearly unacceptable" for residential uses. In addition, Section 65302(f) of the California Government Code requires each county and city in the State to prepare and adopt a comprehensive long-range general plan for its physical development, with Section 65302(g) requiring a noise element to be included in the general plan. The noise element must (1) identify and appraise noise problems in the community, (2) recognize Office of Noise Control guidelines, and (3) analyze and quantify current and projected noise levels.

DHS's Office of Noise Control has established guidelines to provide communities with noise environments that it deems to be generally acceptable based on land-use categories. These guidelines serve as a primary tool for a city to use to assess the compatibility between land uses and outdoor noise. Noise exposure for single-family uses is normally acceptable when the CNEL at exterior residential locations is equal to or below 60 dBA, conditionally acceptable when the CNEL is between 55 to 70 dBA, and normally unacceptable when the CNEL exceeds 70 dBA. Some overlap exists between categories. These guidelines apply to noise sources such as vehicular traffic, aircraft, and rail movements.

Vibration Standards

The California Department of Transportation (Caltrans) published its *Transportation and Construction Vibration Guidance Manual* in September 2018.¹⁶ The manual provides practical guidance to Caltrans engineers, planners, and consultants who must address vibration issues associated with the construction, operation, and maintenance of Caltrans projects. This manual provides guidelines for assessing vibration damage potential to various types of buildings, ranging from 0.08 to 0.12 inches per second for extremely fragile historic buildings, ruins, and ancient monuments, to 0.50 to 2.0 inches per second for modern industrial and commercial buildings.

The guidance and procedures provided in the Caltrans manual should be treated as screening tools for assessing the potential for adverse effects related to human perception and structural damage. General information on the potential effects of vibration on vibration-sensitive research and advanced-technology facilities is also provided, but a discussion of detailed assessment methods in this area is beyond the

State of California, Governor's Office of Planning and Research, *General Plan Guidelines 2017* (2018), 374, accessed December 2018, http://opr.ca.gov/planning/general-plan/guidelines.html.

California Department of Transportation (Caltrans), *Transportation and Construction Vibration Guidance Manual*, September 2018, accessed May 2019, https://www.transit.dot.gov/sites/fta.dot.gov/files/docs/research-innovation/118131/transit-noise-and-vibration-impact-assessment-manual-fta-report-no-0123_0.pdf.

manual's scope. The document is not an official policy, standard, specification, or regulation. Therefore, the vibration analysis in this Draft EIR is based on the FTA's standards and the Caltrans standards are included for informational purposes only.

State of California Building Code

California's noise insulation standards are codified in the California Code of Regulations, Title 24, Building Standards Administrative Code, Part 2, California Building Code. These noise standards are applied to new construction in California for the purpose of interior noise compatibility from exterior noise sources. The regulations specify that acoustical studies must be prepared when noise-sensitive structures, such as residential buildings, schools, or hospitals, are located near major transportation noise sources, and where such noise sources create an exterior noise level of 60 dB(A) CNEL or higher. Acoustical studies that accompany building plans must demonstrate that the structure has been designed to limit interior noise in habitable rooms to acceptable noise levels. For new residential buildings, schools, and hospitals, the acceptable interior noise limit for new construction is 45 dB(A) CNEL.

California Noise Insulation Standards

The California Noise Insulation Standards¹⁷ require that interior noise levels from exterior sources be 45 dB(A) or less in any habitable room of a multiresidential use facility (e.g., hotels, motels, dormitories, long-term care facilities, and apartment houses, except detached single-family dwellings) with doors and windows closed. Measurements are based on CNEL or Ldn (the day–night average), whichever is consistent with the noise element of the local general plan. Where exterior noise levels exceed 60 dB(A) CNEL, an acoustical analysis for new development may be required to show that the proposed construction will reduce interior noise levels to 45 dB(A) CNEL. If the interior 45 dB(A) CNEL limit can be achieved only with the windows closed, the residence must include mechanical ventilation that meets applicable *Uniform Building Code* (UBC) requirements.

California Department of Health Services

The State of California Department of Health Services, Environmental Health Division, has published recommended guidelines for noise and land use compatibility, referred to as the *State Land Use Compatibility Guidelines for Noise* ("State Noise Guidelines"). The State Noise Guidelines, illustrated in **Figure 5.11-6: Land Use Compatibility to Noise**, indicate that residential land uses and other noise-sensitive receptors generally should locate in areas where outdoor ambient noise levels do not exceed 65 to 70 dB(A) CNEL. According to the *State Noise Guidelines*, an exterior noise level of 60 dB(A) CNEL is

¹⁷ California Code of Regulation, Title 24, sec. 3501 et seq.

considered to be "normally acceptable" for single-family, duplex, and mobile homes involving normal, conventional construction, without any special noise insulation requirements. Exterior noise levels up to 65 dB(A) CNEL are typically considered "normally acceptable" for multifamily units and transient lodging without any special noise insulation requirements. Between these values and 70 dB(A) CNEL, exterior noise levels are typically considered "conditionally acceptable," and residential construction should only occur after a detailed analysis of the noise reduction requirements and needed noise attenuation features have been included in the Project design. Exterior noise attenuation features include, but are not limited to, setbacks to place structures outside the conditionally acceptable noise contour, orienting structures so no windows open to the noise source, and/or installing noise barriers such as berms and/or solid walls.

Regional and Local

City of Rancho Mirage Noise Ordinance

The City's Municipal Health and Safety Code set forth standards, guidelines, and procedures concerning the regulation of noise in Rancho Mirage. Section 8.45 of the Municipal Code cites the value and importance given by residents, visitors, and business to the exceptional quality of life and peace and quiet of the community. Pursuant to the City Noise Ordinance, the City restricts noise generated at a property from exceeding certain noise levels for extending periods of time to protect people from objectionable nontransportation noise sources.

According to Section 8.45.050, Special Provisions and Exceptions, of the City's Municipal Code, construction, alternation, repair, grading or improvement of any building, structure, road, or improvement to real property for which a permit has been issued is exempt from the City's noise ordinance so long as construction activities occur within normal business hours (7:00 AM to 7:00 PM, except on Sundays).

The Rancho Mirage Noise Ordinance provides definition of key terms and defines exterior noise level standards on a time-of-day basis along with adjustments for intensity and duration. The appropriate exterior noise standards are identified in **Table 5.11-7: City of Rancho Mirage Exterior Noise Limits**. ¹⁸

_

FIGURE **5.11-6**

Land Use Compatibility to Noise

B. ENVIRONMENTAL IMPACTS

1. Threshold of Significance

In order to assist in determining whether a project would have a significant effect on the environment, the City finds a project may be deemed to have a significant noise impact, if it would result in the:

Threshold 5.11-1: Generation of a substantial temporary or permanent increase in ambient noise levels in the vicinity of the project in excess of standards established in the local general plan or noise ordinance, or applicable standards of other agencies.

Based on State and local noise criteria, the following would be considered significant:

- Noise generated by buildout of Section 31 Specific Plan would result in stationary equipment (nontransportation) noise that results in a nuisance at noise sensitive receptors based on stationary noise limits of the Rancho Mirage Municipal Code.
- New noise sensitive uses would be located in a noise environment that
 exceeds the State's noise compatibility guidelines. Similar to State
 guidelines, it is the policy of the City to require new residential development
 to achieve an interior noise environment of 45 dB(A) CNEL or exterior noise
 levels at single family residential noise sensitive areas to 65 dB(A) CNEL.

Based on local noise criteria established in the City's General Plan, the following would be considered significant:

- An increase of three dB(A) or greater in traffic noise levels that occur from project-related activities would be significant if the resulting noise levels exceeded the Noise Compatibility Matrix for "acceptable" exterior noise levels.
- An increase of five dB(A) or less in traffic noise levels that occur from project-related activities would not be considered significant if the resulting noise levels remain below the "acceptable" thresholds established by the State and City. Increases in traffic noise greater than 5 dB(A) would be considered to be significant.

Based on local noise criteria established by the City, the following would be considered significant:

Construction activities occurring outside the normal business hours of 7:00
 AM and 7:00 PM, except Sundays and holidays.

Threshold 5.11-2: Generation of excessive groundborne vibration or groundborne noise levels.

Based on vibration criteria established by the Federal Transit Administration, the following would be considered significant:

Construction equipment would produce perceptible levels of vibration (78
 VdB) during the daytime at off-site vibration sensitive structures.

2. Methodology

Ambient Noise Measurements

To establish baseline noise conditions, existing ambient noise levels, as described above, were monitored at the eight representative locations within the vicinity of the Project site. These monitored noise levels serve as the baseline for the analysis of Proposed Project impacts. The baseline noise-monitoring program was conducted on April 19, 2019, using a Larson Davis 831 Type 1 Sound Level Meter, compliant with Section 8.45.040 of the City's Municipal Code. 15-minute measurements were conducted at each of the receptor locations.

Construction

On-Site Construction Activities

Construction activities typically generate noise from the operation of equipment required for construction of various facilities. Noise impacts from on-site construction and staging of construction trucks were evaluated by determining the noise levels generated by different types of construction activity, calculating the construction-related noise level at nearby noise-sensitive receptor locations, and comparing these construction-related noise levels to existing ambient noise levels (i.e., noise levels without Plan-related construction noise). The actual noise level would vary, depending upon the equipment type, model, the type of work activity being performed, and the condition of the equipment.

In order to calculate a construction CNEL, hourly activity or utilization factors (i.e., the percentage of normal construction activity that would occur, or construction equipment that would be active, during each hour of the day) are estimated based on the temporal characteristics of other previous and current construction projects. The hourly activity factors express the percentage of time that construction activities would emit average noise levels. Typical noise levels for each type of construction equipment were obtained from the Federal Highway Administration's (FHWA) Roadway Construction Noise Model. Calculated noise levels associated with construction at noise-sensitive receptor locations were then

compared to estimated existing noise levels and the construction noise significance thresholds identified below.

Construction Traffic Noise

The analysis of construction traffic noise impacts focuses on off-site areas by: (1) identifying major roadways that may be used for construction worker commute routes or truck haul routes; (2) generally identifying the nature and location of noise-sensitive receptors along those routes; and (3) evaluating the traffic characteristics along those routes, specifically as related to existing traffic volumes. Construction traffic volume and road parameter data would be input into the FHWA TNM model to calculate average noise levels for these trips. Construction trucks staging and hauling route noise impacts would be evaluated by determining the noise levels generated by different types of construction activity, calculating the construction-related noise levels to existing ambient noise levels (i.e., noise levels without construction noise).

Construction Equipment Vibration

Construction activity can result in varying degrees of ground vibration, depending on the equipment and methods employed. Operation of construction equipment causes ground vibrations that spread through the ground and diminish in strength with distance. While ground vibrations from construction activities do not often reach the levels that can damage structures, fragile buildings must receive special consideration.

Impacts due to construction activities were evaluated by identifying vibration sources (i.e., construction equipment), measuring the distance between vibration sources and surrounding structure locations, and making a significance determination.

For quantitative construction vibration assessments related to building damage and human annoyance, vibration source levels for construction equipment is taken from the FTA *Transit Noise and Vibration Impact Assessment Manual*. Building damage would be assessed for each piece of equipment individually and assessed in terms of peak particle velocity. Ground-borne vibration related to human annoyance is assessed in terms of rms velocity levels.

The vibration source levels for various types of equipment are based on data provided by the FTA.

Operation

Roadway Noise

Traffic noise levels were modeled using the FHWA TNM. The FHWA TNM calculates noise associated with a specific line source and the results characterize noise generated by motor vehicle travel along a specific roadway segment. The traffic noise impact analysis is based on the 24-hour CNEL noise descriptor and incorporates traffic volumes, vehicle mix, posted speed limits, roadway geometry, and site conditions. Future conditions take into account the 2040 Southern California Association of Governments (SCAG) land use dataset which includes all pending and approved development projects within the City. Noise levels were evaluated with respect to the following traffic scenarios:

- Existing (2018) Conditions;
- Existing (2018) plus Proposed Project Conditions;
- Future (2040) without Proposed Project Conditions; and
- Future (2040) plus Proposed Project Conditions.

Noise impacts due to off-site motor vehicle travel were analyzed by comparing the projected increase in traffic noise levels from Existing without Project conditions to both Existing plus Proposed Project and Future plus Proposed Project to the applicable significance criteria.

Cumulative noise impacts due to off-site motor vehicle travel were analyzed by comparing the projected increase in traffic noise levels from Existing without Project conditions to Future plus Project conditions to the applicable significance criteria. Future plus Project conditions include traffic volumes from future ambient growth, related projects, and the Proposed Project.

Operation Vibration

The majority of the Project's operational-related vibration sources, such as mechanical and electrical equipment, would incorporate vibration attenuation mounts, as required by the particular equipment specifications. Therefore, operation of the Project would not increase the existing vibration levels in the immediate vicinity of the Project and, as such, vibration impacts associated with the Project would be minimal. Therefore, the ground borne vibration analysis is limited to Project-related construction activities.

3. Project Design Features

The following **Project Design Features (PDFs)** are incorporated into the proposed Project and would reduce potential noise impacts:

PDF 5.11-1: Residential Planning Areas 1, 2, and 3 would be gated communities with a perimeter wall to provide privacy and a noise barrier from adjacent arterial roadways. Perimeter walls of the residential communities would be 6 feet in height and the Town Center would include a maximum of 3-feet high perimeter walls.

4. **Project Impacts**

Threshold 5.11-1:

Would the project result in the generation of a substantial temporary or permanent increase in ambient noise levels in the vicinity of the project in excess of standards established in the local general plan or noise ordinance, or applicable standards of other agencies?

Construction

Noise impacts from Project construction activities would result from the noise generated by the amount of construction equipment, the location of the equipment, the timing and duration of the noise-generating construction activities, and the relative distance to noise-sensitive receptors. Construction activities would include: grading, building construction, and building finishing. Each stage of construction would involve the use of various types of construction equipment and would, therefore, have its own distinct noise characteristics. Noise from construction equipment would generate both steady-state and episodic noise that could be heard within and adjacent to the Project site. In addition to these on-site sources, construction would include off-site truck travel associated with the hauling of excavated materials from the Project site, as well as the delivery of construction materials, including concrete. The analysis of noise levels associated with on-site construction activities as well as off-site truck travel is provided below under separate subheadings. In addition, vibration levels associated with on-site construction activities are evaluated in terms of impacts to both off-site buildings and humans.

On-Site Construction Activities

Individual pieces of construction equipment that would most likely be used for construction within the Project site produce maximum noise levels of 74 dBA to 85 dBA at a reference distance of 50 feet from the noise source, as shown in **Table 5.11-8: Typical Maximum Noise Levels for Construction Equipment**. The construction equipment-reference noise levels are based on measured noise data compiled by the FHWA. These maximum noise levels would occur when equipment is operating under full power conditions. However, equipment used on construction sites typically operate at less than full power. The acoustical usage factor is the percentage of time that each type of construction equipment is anticipated

to be in full power operation during a typical construction day. These values are estimates and will vary based on the actual construction process and schedule.

Table 5.11-8

Typical Maximum Noise Levels for Construction Equipment

| Type of Equipment | Reference Maximum Noise Levels at 50 Feet, dBA (Lmax) | Acoustical Usage Factor (%) |
|-------------------------|---|--------------------------------|
| Air compressor | 78 | 40 |
| Cement and mortar mixer | 80 | 50 |
| Concrete mixer truck | 79 | 40 |
| Concrete pump | 81 | 20 |
| Crane | 81 | 16 |
| Dozer | 82 | 40 |
| Drill Rig | 84 | 20 |
| Excavator | 81 | 40 |
| Forklift | 75 | 20 |
| Generator | 81 | 50 |
| Grader | 85 | 40 |
| Dump/Haul truck | 76 | 40 |
| Paver | 77 | 50 |
| Rollers | 80 | 20 |
| Rubber-tire loader | 79 | 40 |
| Tractor/Loader/Backhoe | 84 | 40 |
| Delivery truck | 74 | 40 |
| Water truck | 82 | 10 |
| Welders | 74 | 40 |

Source: FHWA Roadway Construction Noise Model User's Guide (2006), Table 1.

To characterize construction-period noise levels, the average (hourly Leq) noise level associated with each construction stage was calculated based on the quantity, type, and usage factors for each type of equipment that would be used during each construction stage. These noise levels are typically associated with multiple pieces of equipment operating simultaneously. Site grading typically requires the use of earth moving equipment, such as excavators, graders, dozers, scrapers, and tractors/loaders/backhoes. Building construction typically involves the use of cranes, forklifts, generators, tractors/loaders/backhoes,

¹ Construction equipment noise levels are based on the FHWA Roadway Construction Noise Model.

and welders. Paving typically involves the use of pavers, paving equipment, and rollers. Architectural coating typically involves air compressors.

Equipment estimates, and noise levels used for the analysis during the construction phases are representative of worst-case conditions because it is unlikely that all construction equipment contained on the Project site would operate simultaneously. Construction equipment operates at its nosiest levels for certain percentages of time during operation. Equipment such as graders, dozers, and scrapers would operate at different percentages over the course of an hour. ¹⁹ Forecasts of construction noise levels are shown in **Table 5.11-9**: **Construction Noise Levels**, which presents construction noise levels generated by on-site construction equipment at each monitored site.

Table 5.11-9
Construction Noise Levels

| | _ | Estimated Noise Levels by Construction Phase (dBA Leq) | | | | Maximum Increase |
|----------|-----------------------------------|--|--------------------------|--------|--------------------------|-----------------------------------|
| Location | Ambient Noise Levels (dbA Leq) | Grading | Building Construction | Paving | Architectural Coating | Over Ambient (without mitigation) |
| Site 1 | 73.6 | 90.5 | 84.2 | 77.0 | 69.1 | +16.9 |
| Site 2 | 70.6 | 84.2 | 78.0 | 70.7 | 62.8 | +13.6 |
| Site 3 | 69.3 | 87.9 | 81.6 | 74.4 | 66.5 | +18.6 |
| Site 4 | 71.9 | 87.5 | 81.2 | 74.0 | 66.1 | +15.6 |
| Site 5 | 72.2 | 84.5 | 78.2 | 71.0 | 63.1 | +12.3 |
| Site 6 | 69.8 | 91.0 | 84.8 | 77.5 | 69.6 | +21.2 |
| Site 7 | 69.5 | 91.0 | 84.8 | 77.5 | 69.6 | +21.5 |
| Site 8 | 73.7 | 87.5 | 81.2 | 74.0 | 66.1 | +13.8 |

Source: RCNM Version 1.1

Refer to Appendix H.3 for construction noise work sheets.

Implementation of Mitigation Measure **MM 5.11-1** would provide noise abatement during construction near adjacent receptors. Mitigation Measure **MM 5.11-1** would include the use of optimal muffler systems for all equipment and the break in line of sight to a sensitive receptor would reduce construction noise levels by approximately 10 dB or more.²⁰ In addition, Mitigation Measure **MM 5.11-1** would limit the number of noise-generating heavy-duty off-road construction equipment (e.g., backhoes, dozers,

¹⁹ DOT, Federal Highway Administration (FHWA), Traffic Noise Model (2006).

²⁰ FHWA, Special Report – Measurement, Prediction, and Mitigation, updated June 2017. https://www.fhwa.dot.gov/Environment/noise/construction_noise/special_report/hcn04.cfm, accessed November 2018.

excavators, loaders, rollers, etc.) simultaneously used on the Project site within 150 feet of off-site noise sensitive receptors surrounding the site and would further reduce construction noise levels by 5 dBA. Furthermore, limiting the number of operating equipment to two within 150 feet of off-site sensitive receptors surrounding site would further reduce construction noise levels by approximately 7 dBA.²¹ As shown in **Table 5.11-9**, construction noise levels would increase by a maximum of 21.5 dBA above ambient at Site 7. With implementation of Mitigation Measure **MM 5.11-1**, construction noise would be reduced by, at a minimum, 22 dB, and would not increase the ambient noise levels. As such impacts would be less than significant with mitigation incorporated.

Off-Site Construction Activities

Off-site construction noise, as detailed in the methodology section above, has been forecasted using the FHWA TNM and is based on forecasted haul truck activity as well as the delivery of building materials, including concrete. The FHWA TNM was used to calculate the hourly Leq noise levels generated by construction-related trucks. Noise impacts were determined by comparing the predicted noise level with that of the existing ambient noise levels along the anticipated truck travel routes. At the maximum, construction would include approximately 372 worker trips per day including 121 vendor trips per day (refer to **Appendix C** for Air Quality Output sheets for each Phase of construction). Based on these trips, roadway noise levels would result in approximately 50 dBA CNEL at 75 feet from the receptor. As indicated therein, the estimated noise levels due to off-site construction truck travel would be below existing ambient noise levels. Thus, Proposed Project noise impacts attributable to off-site construction truck travel would be less than significant.

Operation

The Project would generate an estimated 26,408 daily trips, which includes both internal trips (3,644) and external trips (22,764). As mentioned previously, to estimate noise level increase and impacts due to the Project, noise level increases were calculated from the traffic volumes provided in the Traffic Study (refer to **Appendix I**). **Table 5.11-10: Existing plus Project Roadway Noise Levels**, illustrates the change in CNEL from existing traffic volumes and from traffic generated by the Project. The difference in traffic noise between existing conditions and existing plus Project conditions represents the increase in noise attributable to Project-related traffic. As shown in **Table 5.11-10**, Project-related traffic would not cause noise levels along the analyzed roadways to increase by more than 3.0 dB(A). The maximum noise level increase along existing roadways would be 1.4 dBA along the I-10 Ramps, west of Bob Hope Drive

City of Rancho Mirage 5.11-36 Section 31 Specific Plan Project
Meridian Consultants July 2019

²¹ Based on the assumption used in the RCNM, 12 scrapers would generate noise levels of up to 85.8 dBA within 85 feet. With optimal exhaust mufflers and limiting to 2 scrapers within 150 feet, noise levels from the scrapers would be 63.1 dBA at the noise sensitive receptor.

(Intersection 1) during the AM peak hour and 1.8 dB(A) along Gerald Ford Drive, west of Monterey Avenue (intersection 16) during the PM peak hour. Consequently, traffic noise levels would not increase by 3 dBA or greater and noise impacts under the Existing plus Project scenario would be less than significant.

Stationary Noise

Parking Lots

Development of the Project would introduce parking lots associated with retail-commercial, resort flex, mixed core uses on the Project Site. Generally, noise associated with parking lots is not of sufficient volume to exceed community noise standards based on the time-weighted CNEL scale. Parking lots can be a source of annoyance due to automobile engine start-ups and acceleration, and the activation of car alarms. Parking lots can generate Lea noise levels of between 49 dB(A) Lea (tire squeals) to 74 dB(A) Lea (car alarms) at 50 feet. Existing off-site residential land uses along Gerald Ford Drive and Frank Sinatra Drive, and proposed on-site multifamily uses along internal roadways would be the closest sensitive receptors and would thus represent the worst-case impact associated with parking lot noise from the Project. Due to the existing level of traffic noise along area roadways, noise would not likely be audible due to the masking of noise by traffic. However, single noise events could be an annoyance to on-site and surrounding residents during certain time periods such as evening and morning hours and may exceed local standards at receptor locations. Implementation of Mitigation Measure MM 5.11-2 would require sound attenuation measures be incorporated into the design to minimize noise levels generated from the parking lots. In addition, acoustical analysis would be prepared to ensure noise levels on sensitive uses would be within the City exterior noise level L50 standard of 60 dB(A) between 7:00 AM and 6:00 PM, 55 dB(A) between 6:00 PM and 10:00 PM, and 50 dB(A) between 10:00 PM and 7:00 AM. Impacts would be reduced to less than significant with mitigation incorporated.

Loading Docks

External truck loading and unloading docks associated with the Project would introduce potential stationary noise sources. These sources would primarily be associated with the retail and commercial, resort flex, and mixed-use core uses. The specific location of potential loading docks has not been determined. The operations at loading docks typically result in noise levels of 64 to 66 dB(A) at 75 feet. The noise from loading docks would not cause an increase in long-term average noise of more than 5 dB(A) on the time-weighted CNEL scale, and would not be significant from that perspective. However, single noise events could be an annoyance during certain time periods such as evening and morning hours to existing on-site and off-site residential land uses and internal roadways. Noise levels may exceed local standards. Implementation of Mitigation Measure MM 5.11-3 would require sound attenuation measures be incorporated into the design to minimize noise levels generated from loading docks. In addition, acoustical analysis would be prepared to ensure noise levels on sensitive uses would be within the City exterior noise level L50 standard of 60 dB(A) between 7:00 AM and 6:00 PM, 55 dB(A) between 6:00 PM and 10:00 PM, and 50 dB(A) between 10:00 PM and 7:00 AM. Impacts would be reduced to less than significant with mitigation incorporated.

HVAC Systems

The Project would introduce various stationary noise sources, including HVAC systems, which would be located either on the roof, the side of a structure or on the ground. Off-site and on-site sensitive receptors could be potentially affected by the introduction of such equipment. Typically, this type of equipment produces noise levels of approximately 56.0 dB(A) at 50 feet from the source. This equipment would be screened and integrated in architectural design of the building, and would further attenuate sound emanating from the HVAC systems. As the sound distance doubles to 100 feet from the equipment, sound levels would be 50 dB(A), which would be below the local exterior noise limits (50 dB(A) between 10:00 PM and 7:00 AM for the City of Rancho Mirage). The use of such equipment would not generate noise levels that would substantially elevate the ambient noise environment and would not generate substantial noise and impacts to nearby noise-sensitive receptors. Impacts would be less than significant.

Human Activity Related Noise

Future residents located on the Project site, as well as nearby sensitive receptors, may experience increases in noise due to an increase in human activity within the area either from people living on the premises, utilizing the on-site amenities including common areas, and the outdoor commercial and mixed-use areas. Potential residential and commercial types of noise include people talking, doors slamming, stereos, and other noise associated with human activity. These noise sources are not unique and generally contribute to ambient noise levels experiences in all land use areas. Maximum permissible noise levels for mixed use areas are typically 55 to 65 dB(A) between 7:00 AM and 6:00 PM. Overall, the noise generated by the Project's land uses would be consistent with the ambient noise levels in the Project Site, which range from 66 to 76 dB(A). Accordingly, impacts would be less than significant.

Threshold 5.11-2: Would the project result in the generation of excessive groundborne vibration or groundborne noise levels?

Construction

On-Site Construction Vibration

Table 5.11-11: On-Site Construction Vibration Impacts—Building Damage and Table 5.11-12: On-Site Construction Vibration—Human Annoyance presents the construction vibration impacts associated with on-site construction in terms of building damage and human annoyance, respectively. As shown in Table 5.11-11, the forecasted vibration levels due to on-site construction activities would not exceed the building damage significance threshold for all sites surrounding the Project area during construction. Therefore, on-site construction vibration would not result in a significant vibration impact with regard to building damage.

Table 5.11-11
On-Site Construction Vibration Impacts—Building Damage

- b Vibration level calculated based on FTA reference vibration level at a 25-foot distance.
- FTA criteria for engineered concrete and masonry buildings.

As shown in **Table 5.11-12**, the forecasted vibration levels due to on-site construction activities would exceed the human annoyance significance thresholds for all site surrounding the Project. With implementation of Mitigation Measure **MM 5.11-1**, limiting the number of noise-generating heavy-duty off-road construction equipment operating simultaneously within 150 feet of off-site noise sensitive receptors surrounding the site would reduce vibration levels by approximately 22 VdB. As shown in **Table 5.11-12**, vibration levels for a vibratory roller would be reduced to 94 VdB at 25 feet. With implementation of Mitigation Measure **MM 5.11-1**, would reduce vibration levels to 72 VdB, below the 78 VdB perceptible levels of vibration. Therefore, on-site construction vibration would not result in a significant vibration impact with regard to human annoyance.

Table 5.11-12
Construction Vibration Impacts-Human Annoyance

Refer to Appendix H.3 for construction vibration worksheets.

Notes: **Boldface type** indicates vibration levels in exceedance of the significance threshold. Ips = inches per second; PPV = peak particle velocity.

Off-Site Construction Vibration

In addition to on-site construction activities, construction delivery/haul trucks would generate ground-borne vibration as they travel along the Projects anticipated off-site truck travel routes. Based on the FTA data, the vibration generated by a typical heavy-duty truck would be approximately 71 VdB (0.015 PPV) at a distance of 75 feet from the truck.²² This forecasted vibration level would be well below the most stringent building damage criteria of 0.12 PPV. Therefore, vibration impacts with respect to building damage from off-site construction truck travel on public roadways would be less than significant.

In addition, vibration sensitive uses (e.g., residential, hotel) are located along Gerald Ford Drive to the north, Frank Sinatra Drive to the south, and Monterey Avenue to the east. Ground-borne vibration levels generated by off-site construction truck travel would be below the 78 VdB significance threshold, as these uses are located more than 75 feet from the truck travel pathway. Thus, vibration impacts with respect to

²² FTA, "Transit Noise and Vibration Impact Assessment," May 2006, Figure 7-3.

human annoyance from off-site construction truck travel would be less than significant for the vibration sensitive land uses located along these roadways.

Operation

Similar to existing conditions, the primary sources of vibration associated with operation would include passenger-vehicle circulation within the Project area and on-site truck activity. Ground-borne vibration typically attenuates rapidly as a function of distance from the vibration source. Furthermore, the majority of the Project's operation-related vibration sources, such as mechanical equipment, would incorporate vibration attenuation mounts as required by the particular equipment specifications. Therefore, operation would not substantially increase existing vibration levels in the immediate vicinity of the Project site. Therefore, vibration impacts associated with operation would be less than significant.

5. Cumulative Impacts

Construction

Noise

Noise impacts are localized in nature and decrease with distance. Cumulative construction noise impacts have the potential to occur when multiple construction projects in the local area generate noise within the same time frame and contribute to the local ambient noise environment. Based on noise levels generated by construction activities associated with the Project and the proximity of both on- and off-site receptors, construction noise from the Project would contribute to the cumulative noise environment. It is expected that, as with the Project, the related projects would implement Best Management Practices (BMPs), which would minimize any noise-related nuisances during construction. Therefore, combined construction noise impact of the related projects and the Project's contribution would not cause a significant cumulative impact. Consequently, impacts would be less than significant with mitigation incorporated.

Vibration

As discussed above, vibration impacts are generally less than significant when the receptor is more than 25 feet from the vibration source. There are no identified project anticipating construction concurrently with the Project and within 25 feet of the sensitive receptors that could be affected by construction. As such, there would be no cumulative sources of construction vibration and no cumulative impact. Impacts would be less than significant.

Operational

Traffic volumes for the future scenario consists of existing counts plus the addition of growth derived from the Rancho Mirage General Pan Model (RMGPM). The RMGPM was updated to be consistent with the

2016 Southern California Association of Governments (SCAG) Regional Transportation Plan (RTP) and Sustainable Communities Strategy (SCS) growth projections. In addition, the pending and approved development projects not included in the City of Rancho Mirage General Plan Model were also included in future projections including: Section 24 Specific Plan, Rancho Mirage Country Club, Agua Caliente Resort and Casino Expansion, the General Plan Zoning Map Amendment, and other changes in zoning designations within the City.

Table 5.11-13: Future (Year 2040) Plus Project Roadway Noise Levels, illustrates the change in CNEL from Year 2040 ambient conditions and from buildout. The Year 2040 ambient conditions represent traffic growth or cumulative development within the Project Site. As shown in Table 5.11-13, Project-related traffic would not cause noise levels along the analyzed roadways to increase by more than 3.0 dB(A). The maximum noise level increase along future roadways would be 0.9 dBA along Gerald Ford Drive, West of Monterey Avenue (Intersection 16) during the AM peak hour and 1.3 dB(A) along I-10 Ramps, west of Portola Road (Intersection 11) during the PM peak hour. As such, impacts related to cumulative roadway noise levels would be less than significant.

C. MITIGATION MEASURES

The following mitigation measures have been identified to mitigate noise impacts:

- **MM 5.11-1:** The project applicant shall require that the following construction best management practices (BMPs) be implemented by contractors to reduce construction noise levels below the City's established thresholds:
 - Ensure that construction equipment is properly equipped with optimal muffler systems according to industry standards and in good working condition.
 - Place noise-generating construction equipment and locate construction staging areas away from sensitive uses, where feasible.
 - Limit the number of noise-generating heavy-duty off-road construction equipment (e.g., backhoes, dozers, excavators, loaders, rollers, etc.) to two (2) pieces of equipment operating simultaneously within 150 of off-site noise sensitive receptors surrounding the site.
 - Stationary construction equipment, such as pumps, generators, or compressors, must be placed as far from noise sensitive uses as feasible during all phases of project construction.
 - Implement noise attenuation measures to the extent feasible, which may include, but are not limited to, temporary noise barriers, such as solid walls and berms, or noise blankets around stationary construction noise sources.
 - Use electric air compressors and similar power tools rather than diesel equipment, where feasible.
 - Construction-related equipment, including heavy-duty equipment, motor vehicles, and portable equipment, must be turned off when not in use for more than 30 minutes.
 - Construction hours, allowable workdays, and the phone number of the job superintendent must be clearly posted at all construction entrances to allow for surrounding owners and residents to contact the job superintendent. If the City or the job superintendent receives a complaint, the superintendent must investigate, take appropriate corrective action, and report the action taken to the reporting party. Contract specifications must be included in the proposed Project construction documents, which must be reviewed by the City prior to issuance of grading permits.

MM 5.11-2: Sound attenuation measures shall be incorporated into the design of individual projects to minimize noise from parking lots. These measures could include, but are not limited to, a noise barrier of sufficient size to break the line of sight, an open-space buffer, a setback, or a combination of methods shall be developed along locations between parking lot noise and exterior usable areas within on-site and adjacent residential uses where these uses interface. Acoustical analysis shall be performed to demonstrate that the parking lot does not result in noise levels on sensitive uses within the City that exceed the City Municipal Code L50 standard of 60 dB(A) between 7:00 AM and 6:00 PM, 55 dB(A) between 6:00 PM and 10:00 PM, and 50 dB(A) between 10:00 PM and 7:00 AM. These components shall be incorporated into the plans submitted by the applicant to the City, prior to the issuance of building permits.

MM 5.11-3: Sound attenuation measures must be incorporated into the design of individual projects to minimize noise from loading docks so that noise levels stay remain below the City's established thresholds. These measures may include, but are not limited to, designing loading docks to have either a depressed (i.e., below grade) loading area, an internal bay, or a wall to break the line of sight between on-site and adjacent residential land uses and loading operations. Acoustical analysis shall be performed to demonstrate that the loading dock does not result in noise levels on sensitive uses within the City that exceed the City's L50 standard of 60 dB(A) between 7:00 AM and 6:00 PM, 55 dB(A) between 6:00 PM and 10:00 PM, and 50 dB(A) between 10:00 PM and 7:00 AM. These components must be incorporated into the plans submitted by the applicant to the City for review and approval, prior to issuance of building permits.

D. LEVEL OF SIGNIFICANCE AFTER MITIGATION

Construction Noise

Implementation of Mitigation Measure **MM 5.11-1**, would provide noise abatement during construction near adjacent receptors including: the use of optimal muffler systems for all equipment and the break in line of sight to a sensitive receptor reducing construction noise levels by approximately 10 dB or more; and limiting the number of noise-generating heavy-duty off-road construction equipment (e.g., backhoes, dozers, excavators, loaders, rollers, etc.) to two (2) pieces of equipment operating simultaneously within 150 feet of off-site noise sensitive receptors surrounding the site. With implementation of Mitigation Measure **MM 5.11-1**, construction noise would be reduced by, at a minimum, 22 dB, and would not increase the ambient noise levels. As such impacts related to construction noise would be less than significant with mitigation incorporated.

Construction Vibration

Implementation of Mitigation Measure **MM 5.11-1** would limit the number of noise-generating heavy-duty off-road construction equipment to two (2) pieces of equipment operating simultaneously within 150 feet of off-site noise sensitive receptors surrounding the site would reduce vibration levels by approximately 22 VdB. Construction vibration would be reduced to below the perceptible levels of vibration of 78 VdB at off-site vibration sensitive structures. As such, impacts related to construction vibration would be less than significant with mitigation incorporated.

Operation

Mitigation Measures **MM 5.11-2** and **MM 5.11-3** would require acoustical analysis of the design of the individual projects to reduce stationary noise sources from parking lots and loading docks to a less than significant level.
